Simulation of Basic Test Signals

Aim:

To generate continuous and discrete waveforms for the following:

1. Unit Impulse Signal
2. Bipolar Pulse Signal
3. Unipolar Pulse Signal
4. Ramp Signal
5. Triangular Signal
6. Sine Signal
7. Cosine Signal
8. Exponential Signal
9. Unit Step Signal

Theory:

1.Unit Impulse Signal:

- A signal that is zero everywhere except at one point, typically at t=0 where its value is 1.
- **Mathematically** $\delta(t) = \begin{cases} \infty; t = 0 \\ 0; t \neq 0 \end{cases}$

2.Bipolar Pulse Signal:

- A pulse signal that alternates between positive and negative values, usually rectangular in shape. It switches between two constant levels (e.g., -1 and 1) for a defined duration.
- **Mathematically p(t) = A for $|t| \leq \tau/2$, p(t) = 0 otherwise**

3. Unipolar Pulse Signal:

- A pulse signal that alternates between zero and a positive value. It remains at zero for a specified duration and then jumps to a positive constant level (e.g., 0 and 1).
- **Mathematically p(t) = A for $|t| \leq \tau/2$, p(t) = 0 otherwise (assuming A is positive)**

4. Ramp Signal:

- A signal that increases linearly with time.
- **Mathematically** $r(t) = \begin{cases} t; t \geq 0 \\ 0; t < 0 \end{cases}$

5.Triangular Signal:

- A periodic signal that forms a triangle shape, linearly increasing and decreasing with time, typically between a positive and negative peak.
- **Mathematically: $\Lambda(t) = 1 - |t|$ for $|t| \leq 1$, $\Lambda(t) = 0$ otherwise**

6.Sine Signal:

- A continuous periodic signal. It oscillates smoothly between -1 and 1.
- **Mathematically: $y(t)=A\sin(2\pi ft)$**

7. Cosine Signal:

- A continuous periodic signal like the sine wave but phase-shifted by π\2.
- **Mathematically: $y(t)=A\cos(2\pi ft)$**

8. Exponential Signal:

- A signal that increases or decreases exponentially with time. The rate of growth or decay is determined by the constant a.
- **Mathematically: e^(at)**

9. Unit Step Signal:

- A signal that is zero for all negative time values and one for positive time values.
- **Mathematically** $u(t) = \begin{cases} 1; t \geq 0 \\ 0; t < 0 \end{cases}$

Verification of Sampling Theorem

Aim:

To verify Sampling Theorem.

Theory:

The Sampling Theorem, also known as the Nyquist-Shannon Sampling Theorem, states that a continuous signal can be completely reconstructed from its samples if the sampling frequency is greater than twice the highest frequency present in the signal. This critical frequency is known as the Nyquist rate.

$$f_s \geq 2 \cdot f_{max}$$

Where:

- fs is the sampling frequency (rate at which the signal is sampled),
- fmax is the highest frequency present in the signal.

Applications:

- Digital audio and video processing
- Communication systems
- Image processing
- Medical imaging

Program:

```
clc;
clear all;
close all;
subplot(2,2,1);
t = 0:0.01:1;
f=10;
y = sin(2*pi*f*t);
```

Experiment No: 3 Date: 13/08/24

Linear Convolution

Aim:

To find linear convolution of following sequences with and without built in function.

- 1. x(n) = [1 2 1 1]
  h(n) = [1 1 1 1]
- 2. x(n) = [1 2 1 2]
  h(n) = [3 2 1 2]

Theory:

Linear convolution is a mathematical operation used to combine two signals to produce a third signal. It's a fundamental operation in signal processing and systems theory.

Mathematical Definition:

Given two signals, *x(t)* and *h(t)*, their linear convolution is defined as:

$$\mathbf{y(t) = x(t) * h(t) = \int_{-\infty}^{\infty} x(\tau)h(t-\tau)\, d\tau}$$

Applications:

Filtering: Convolution is used to filter signals, removing unwanted frequencies or noise.

System Analysis: The impulse response of a system completely characterizes its behaviour, and convolution can be used to determine the output of the system given a known input.

Image Processing: Convolution is used for tasks like edge detection, blurring, and sharpening images.

Program:

1. With built-in function:

```
clc;

clear all;

close all;

x1 = input("Enter first Sequence");

h1 = input("Enter second Sequence");

y1 = conv(x1,h1);

disp("The convoluted sequence is: ");
```

```
disp(y1);
l = length(x1);
m = length(h1);
k = l+m-1;
n1 = 0:1:l-1;
n2 = 0:1:m-1;
n3 = 0:1:k-1;
subplot(1,3,1);
stem(n1,x1,"o");
xlabel("n");
ylabel("Amplitude");
title("x(n)");
grid on
xlim([-1 l+1]);
ylim([0 max(x1)+2]);

subplot(1,3,2);
stem(n2,h1,"o");
xlabel("n");
ylabel("Amplitude");
title("h(n)");
grid on
xlim([-1 m+1]);
ylim([0 max(h1)+2]);

subplot(1,3,3);
stem(n3,y1,"o");
xlabel("n");
ylabel("Amplitude");
title("y(n)");
```

```
grid on
xlim([-1 k+1]);
ylim([0 max(y1)+2]);
```

2.Without built-in function:

```
clc;
clear all;
close all;
x1 = input("Enter first Sequence");
h1 = input("Enter second Sequence");
l = length(x1);
m = length(h1);
k = l+m-1;
y1 = zeros(1,k);
for i=1:l
for j=1:m
y1(i+j-1) = y1(i+j-1) + x1(i)*h1(j);
end
end
disp("The convoluted sequence is: ");
disp(y1);

n1 = 0:1:l-1;
n2 = 0:1:m-1;
n3 = 0:1:k-1;
subplot(1,3,1);
stem(n1,x1,"o");
xlabel("n");
ylabel("Amplitude");
title("x(n)");
```

```
grid on
xlim([-1 l+1]);
ylim([0 max(x1)+2]);

subplot(1,3,2);
stem(n2,h1,"o");
xlabel("n");
ylabel("Amplitude");
title("h(n)");
grid on
xlim([-1 m+1]);
ylim([0 max(h1)+2]);

subplot(1,3,3);
stem(n3,y1,"o");
xlabel("n");
ylabel("Amplitude");
title("y(n)");
grid on
xlim([-1 k+1]);
ylim([0 max(y1)+2]);
```

Result:

Performed Linear Convolution using with and without built-in function.

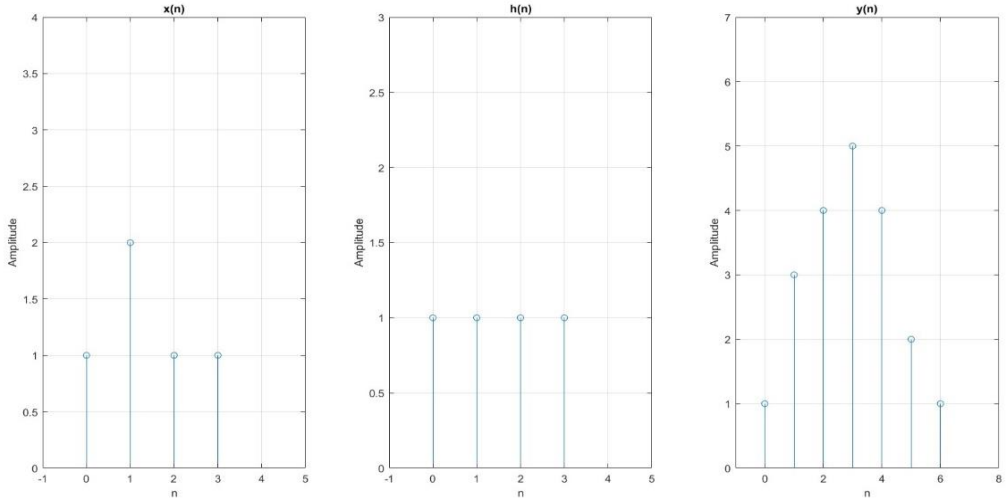
Observation:

a) Enter first Sequence [1 2 1 1]

Enter second Sequence [1 1 1 1]

The convoluted sequence is:

1 3 4 5 4 2 1

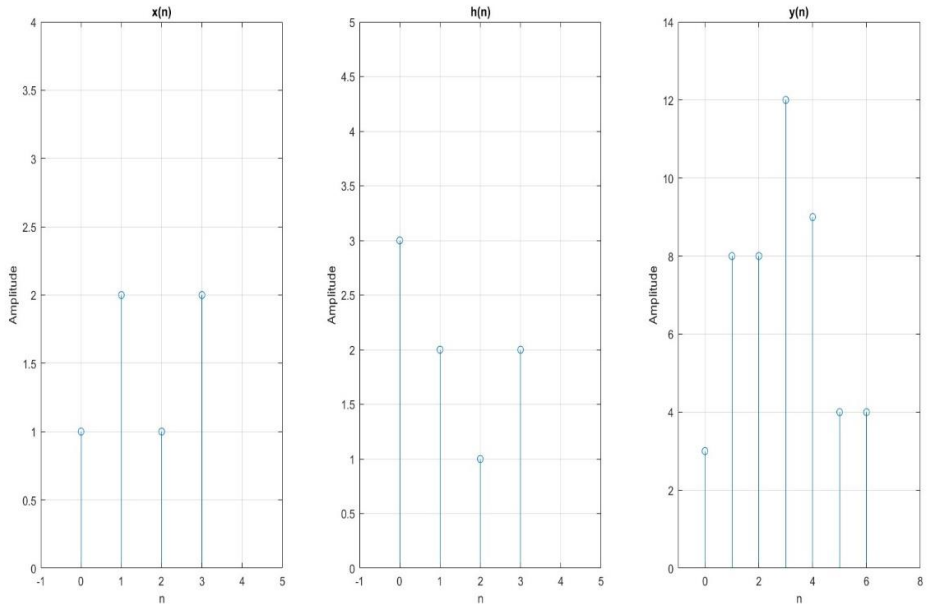


b) Enter first Sequence [1 2 1 2]

Enter second Sequence [3 2 1 2]

The convoluted sequence is:

3 8 8 12 9 4 4



Experiment No: 4 Date: 03/09/24

Circular Convolution

Aim:

To find circular convolution

a. Using FFT and IFFT.
b. Using Concentric Circle Method.
c. Using Matrix Method.

Theory:

Circular convolution is a mathematical operation that is like linear convolution but is performed in a periodic or circular manner. This is particularly useful in discrete-time signal processing where signals are often represented as periodic sequences.

Mathematical Definition:

Given two periodic sequences *x[n]* and *h[n]*, their circular convolution is defined as:

$$y[n] = (x[n] \circledast h[n]) = \sum_{k=0}^{N-1} x[k]h[(n-k) \bmod N]$$

Applications:

- Discrete-Time Filtering: Circular convolution is used for filtering discrete-time signals.
- Digital Signal Processing: It's a fundamental operation in many digital signal processing algorithms.
- Cyclic Convolution: In certain applications, such as cyclic prefix OFDM, circular convolution is used to simplify the implementation of linear convolution.

Program:

a. Using FFT and IFFT.

```
clc;

close all;

clear all;

x1  = [1 2 1 2];

x2 = [1 2 3 4];

X1_k = fft(x1);

X2_k = fft(x2);

Y1_k = X1_k.*X2_k;
```

```
y1 = ifft(Y1_k);
disp("Using FFT and IFFT:")
disp(y1);
```

b. Using Concentric Circle Method.

```
clc;
close all;
clear all;
x  = [1 2 1 2];
h = [1 2 3 4];
N = max(length(x),length(h));
y = zeros(1,N);
for n=1:N
h_s = circshift(h,n-1); %shifting h(n) by 1 unit
y(n) = sum(x.*h_s);
end
disp("Using Concentric Circle Method:")
disp(y);
```

c. Using Matrix Method.

```
clc;
close all;
clear all;
x  = [1 2 1 2];
h = [1 2 3 4];
N = max(length(x),length(h));
h_n = zeros(N,N);
for n=1:N
h_s = circshift(h,n-1);%shifting h(n) by 1 unit
h_n(:,n) = h_s;
```

```
end
y = h_n *x';
disp("Using Concentric Circle Method:")
disp(y');
```

Result:

Linear Convolution using Circular Convolution and Vice versa.

Aim:

1. To perform Linear Convolution using Circular Convolution.
2. To perform Circular Convolution using Linear Convolution.

Theory:

Performing Linear Convolution Using Circular Convolution

Method:

1. **Zero-Padding:**
    - Pad both sequences x[n] and h[n] with zeros to a length of at least 2N-1, where N is the maximum length of the two sequences. This ensures that the circular convolution will not wrap around and introduce artificial periodicity.
2. **Circular Convolution:**
    - Perform circular convolution on the zero-padded sequences.
3. **Truncation:**
    - Truncate the result of the circular convolution to the length N1 + N2 - 1, where N1 and N2 are the lengths of the original sequences x[n] and h[n], respectively.

Example:

Consider the sequences x[n] = [1, 2, 3] and h[n] = [4, 5].

1. Zero-padding:
    - Pad x[n] to [1, 2, 3, 0, 0] and h[n] to [4, 5, 0, 0].
2. Circular Convolution:
    - Perform circular convolution on the zero-padded sequences. The result will be [4, 13, 21, 15, 0].
3. Truncation:
    - Truncate the result to [4, 13, 21, 15].

This result is the same as the linear convolution of x[n] and h[n].

Performing Circular Convolution Using Linear Convolution

Method:

1. **Zero-Padding:**
    - Pad both sequences x[n] and h[n] to a length of at least 2N-1, where N is the maximum length of the two sequences.
2. **Linear Convolution:**
    - Perform linear convolution on the zero-padded sequences.
3. **Modulus Operation:**
    - Apply the modulus operation to the indices of the linear convolution result, using the period N. This effectively wraps around the ends of the sequence, making it circular.

Example:

Using the same sequences as before, x[n] = [1, 2, 3] and h[n] = [4, 5].

1. Zero-padding:
    - Pad x[n] to [1, 2, 3, 0, 0] and h[n] to [4, 5, 0, 0].
2. Linear Convolution:
    - Perform linear convolution. The result will be [4, 13, 21, 15, 0].
3. Modulus Operation:
    - Apply the modulus operation to the indices: [4, 13, 21, 15, 0] becomes [4, 13, 2, 15, 0].

Program:

1. Linear Convolution using Circular Convolution

```
clc;
clear all;
close all;
x = [1 2 3 4];
h = [1 1 1 ];
l = length(x);
m = length(h);
k = l+m-1;
x = [x zeros(1,k-l)];
h = [h zeros(1,k-m)];
```

```
X_k = fft(x);
H_k = fft(h);
Y_k = X_k.*H_k;
y = ifft(Y_k);
disp("Linear Convolution using Circular Convolution :");
disp(y);
```

2.Circular convolution using Linear Convolution

```
clc;
close all;
clear all;
x = [1 2 3 4];
h = [1 1 1 ];
l = length(x);
m = length(h);
lc = max(l,m);
ll= l+m-1;
y = conv(x,h);
for i=1:ll-lc
y(i) = y(i) + y(lc+i);
end
for i=1:lc
y1(i) = y(i);
end
disp("Circular convolution using Linear Convolution:")
disp(y1);
```

Result:

Performed a) Linear Convolution using Circular Convolution; b) Circular Convolution using Linear Convolution and verified result.

DFT AND IDFT

Aim:

1.DFT using inbuilt function, without using inbuilt function and twiddle factor. Also plot magnitude and phase plot of DFT

2.IDFT using inbuilt function, without using inbuilt function, and twiddle factor.

Theory:

Discrete Fourier Transform (DFT)

The **Discrete Fourier Transform (DFT)** is a mathematical transformation used to analyze the frequency content of discrete signals. For a sequence x[n] of length N, the DFT is defined as:

$$\boldsymbol{X[k] = \sum_{n=0}^{N} x[n] \cdot e^{-j\frac{2\pi}{N}nk},\ k = 0, 1, 2, \ldots, N-1}$$

- X[k] is the DFT of the sequence x[n].
- The exponential factor represents $\boldsymbol{e^{-j\frac{2\pi}{N}nk}}$ the complex sinusoidal basis functions.
- The DFT maps the time-domain signal into the frequency domain.

Inverse Discrete Fourier Transform (IDFT)Method:

The **Inverse Discrete Fourier Transform (IDFT)** is used to convert a frequency-domain sequence X[k] back into its time-domain sequence x[n]. The IDFT is defined as:

$$\boldsymbol{x[n] = \frac{1}{N}\sum_{k=0}^{N} X[k] \cdot e^{j\frac{2\pi}{N}nk},\ n = 0, 1, 2, \ldots, N-1}$$

- The IDFT takes the frequency components X[k] and reconstructs the original sequence x[n].
- The exponential factor $\boldsymbol{e^{j\frac{2\pi}{N}nk}}$ is the inverse of the DFT's complex sinusoidal basis functions.

The twiddle factor is a complex number that is used in the Cooley-Tukey algorithm, a fast Fourier transform (FFT) algorithm. It is defined as:

W_N^k = exp(-j * 2 * pi * k / N)

- The twiddle factor represents a rotation in the complex plane by an angle of 2*pi*k/N radians. It is used to combine the results of the smaller FFTs that are computed in the Cooley-Tukey algorithm to obtain the final FFT result.

Application

- Spectrum (Analysis)
- Filtering
- Compression
- Modulation
- Convolution
- Demodulation
- Estimation

Properties of DFT

Aim:

Verify following properties of DFT using Matlab/Scilab.

1.Linearity Property

2.Parsevals Theorem

3.Convolution Property

4.Multiplication Property

Theory:

1. Linearity Property

The linearity property of the DFT states that if you have two sequences x1[n] and x2[n], and their corresponding DFTs are X1[k] and X2[k], then for any scalar a and b:

$$\mathbf{DFT\{a\cdot x1[n]+b\cdot x2[n]\} = a\cdot DFT\{x1[n]\}+b\cdot DFT\{x2[n]\}}$$

2. Parseval's Theorem

Parseval's theorem states that the total energy of a signal in the time domain is equal to the total energy in the frequency domain. For a sequence x[n] and its DFT X[k]:

$$\sum_{n=0}^{N-1}]x[n]^2=\frac{1}{N}\sum_{n=0}^{N-1}X[k]$$

3.Convolution Property

The convolution property of the DFT states that the circular convolution of two sequences in the time domain is equivalent to the element-wise multiplication of their DFTs in the frequency domain:

$$\mathbf{DFT\{x1[n]\circledast x2[n]\}=DFT\{x1[n]\}\cdot DFT\{x2[n]\}}$$

4. Multiplication Property

The multiplication property of DFT states that pointwise multiplication in the time domain corresponds to circular convolution in the frequency domain:

$$\mathbf{DFT\{x1[n]\cdot x2[n]\} = \frac{1}{N}DFT\{x1[n]\}\circledast DFT\{x2[n]\}}$$

Program:

OVERLAP ADD AND OVERLAP SAVE METHOD

Aim:

Implement overlap add and overlap save method using Matlab/Scilab.

Theory:

Both the Overlap-Save and Overlap-Add methods are techniques used to compute the convolution of long signals using the Fast Fourier Transform (FFT). The direct convolution of two signals, especially when they are long, can be computationally expensive. These methods allow us to break the signals into smaller blocks and use the FFT to perform the convolution more efficiently.

Overlap-Save Method

The Overlap-Save method deals with circular convolution by discarding the parts of the signal that are corrupted by wrap-around effects. Here's how it works:

1. Block Decomposition: The input signal is divided into overlapping blocks. If the filter has length and we use blocks of length, the overlap is samples, so each block has new samples and samples from the previous block.

2. FFT and Convolution: Each block is convolved with the filter using FFT. However, because of circular convolution, the result contains artifacts due to the overlap.

3. Discard and Save: We discard the first samples from each block (the part affected by the wrap-around) and save the remaining samples. This gives us the correct linear convolution.

Overlap-Add Method

The Overlap-Add method, on the other hand, handles circular convolution by adding overlapping sections of the convolved blocks. Here's how it works:

1. Block Decomposition: The input signal is split into non-overlapping blocks of size. Each block is then zero-padded to a size of , where is the length of the filter.

2. FFT and Convolution: Each block is convolved with the filter using FFT. Since the blocks are zero-padded, the convolution produces valid linear results, but the output blocks overlap.

3. Overlap and Add: After convolution, the results of each block overlap by samples. These overlapping regions are added together to form the final output.

Program:

1. Overlap Add

```
clc;
clear all;
close all;
% User input for the input sequence
x = input('Enter the input sequence x : ');
% User input for the impulse response
h = input('Enter the impulse response h : ');
% Section length for overlap-save
L = length(h);  % Length of impulse response
% Initialization
N = length(x);
M = length(h);
% Pad input x with zeros
x_padded = [x, zeros(1, L - 1)];
% Prepare the output array
y = zeros(1, N + M +1);
% Calculate the number of sections
num_sections = (N + L - 1) / L;  % Calculate number of sections
% Process sections
for n = 0:num_sections-1
    % Determine the current section
    start_idx = n * L + 1;
    end_idx = start_idx + L - 1;
    % Ensure the section does not exceed the bounds
    x_section = x_padded(start_idx:min(end_idx, end));
    % Convolution
    conv_result = conv(x_section, h);
    % Save the results to the output
```

```
    y(start_idx:start_idx     +     length(conv_result)     -     1)
=y(start_idx:start_idx + length(conv_result) - 1) + conv_result;
end
% Trim the output to the valid part
y = y(1:N + M - 1);
% Compare with built-in convolution
y_builtin = conv(x, h);
% Display results
disp('Overlap-add convolution result:');
disp(y);
disp('Built-in convolution result:');
disp(y_builtin);
% Plotting results
figure;
subplot(2, 1, 1);
stem(y, 'filled');
title('Overlap-add Convolution Result');
grid on;
subplot(2, 1, 2);
stem(y_builtin, 'filled');
title('Built-in Convolution Result');
grid on;
```

2.Overlap Save

```
clc;
clear all;
close all;
% Input the sequences and block size
x = input("Enter 1st sequence: ");
h = input("Enter 2nd sequence: ");
```

```
N = input("Fragmented block size: ");
% Call the overlap-save function
y = ovrlsav(x, h, N);
disp("Using Overlap and Save method");
disp(y);
disp("Verification");
disp(cconv(x,h,length(x)+length(h)-1));
% Define the overlap-save method function
function y = ovrlsav(x, h, N)
    if (N < length(h))
        error("N must be greater than the length of h");
    end
    Nx = length(x);  % Length of input sequence x
    M = length(h);   % Length of filter sequence h
    M1 = M - 1;      % Length of overlap
    L = N - M1;      % Length of non-overlapping part
    % Zero-padding for input and filter sequences
    x = [zeros(1, M1), x, zeros(1, N-1)];
    h = [h, zeros(1, N - M)];
    % Number of blocks
    K = floor((Nx + M1 - 1) / L);
    % Initialize the output matrix Y
    Y = zeros(K + 1, N);

    % Perform block convolution using circular convolution
    for k = 0:K
        xk = x(k*L + 1 : k*L + N);  % Extract block of input sequence
        Y(k+1, :) = cconv(xk, h, N);  % Circular convolution
    end
    % Extract valid part from the result and concatenate
```

```
    Y = Y(:, M:N)';
    y = (Y(:))';
end
```

Result:

Performed Overlap Add and Overlap Save methods and verified the result.

Observation:

1. Overlap Add

Enter the input sequence x : [3 -1 0 1 3 2 0 1 2 1]

Enter the impulse response h : [1 1 1]

IMPLEMENTATION OF FIR FILTERS

Aim:

Implement various FIR filters using different windows

1. Low Pass Filter
2. High Pass Filter
3. Band pass Filter
4. Band stop Filter

Theory:

Design of FIR Filters Using Window Methods

In FIR (Finite Impulse Response) filter design, the goal is to create a filter with specific frequency response characteristics, such as low-pass, high-pass, band-pass, or band-stop. Using window methods, we can shape the filter response by applying a window function to an ideal filter impulse response.

Step 1: Define the Ideal Impulse Response

The ideal impulse response, h_ideal(n), of a low-pass filter with a cutoff frequency f_c is given by:

h_ideal(n) = sin(2 * pi * f_c * (n - (N - 1) / 2)) / (pi * (n - (N - 1) / 2))

Where:

•f_c: Normalized cut off frequency
• N: Filter length
• n: Sample index

Step 2: Select an Appropriate Window Function

The choice of window affects the trade-off between the main lobe width and the sidelobe levels. Common windows include the Rectangular, Hamming, Hanning, Blackman, and Kaiser windows.

Window Type	Formula
Rectangular	w(n) = 1
Triangular	w(n) = 1 - 2*abs(n) / (N - 1)
Hamming	w(n) = 0.54+ 0.46 * cos(2 * pi * n / (N - 1))
Hanning	w(n) = 0.5 * (1 +cos(2 * pi * n / (N - 1)))
Blackman	w(n) = 0.42 + 0.5 * cos(2 * pi * n / (N - 1)) + 0.08 * cos(4 * pi * n / (N - 1))

Kaiser	w(n) = I0(beta * sqrt(1 - (2 * n / (N - 1) - 1)^2)) / I0(beta)

Step 3: Apply the Window to the Ideal Impulse Response

The windowed impulse response is computed as:

$$\mathbf{h(n) = h\_ideal(n) * w(n)}$$

Step 4: Construct the FIR Filter

The final impulse response h(n) defines the FIR filter coefficients that can be used in filtering algorithms.

Filters:

Lowpass:
$$h(n) = \begin{cases} \frac{\Omega_c}{\pi} & n = 0 \\ \frac{\sin(\Omega_c n)}{n\pi} \text{ for } n \neq 0 & -M \leq n \leq M \end{cases}$$

Highpass:
$$h(n) = \begin{cases} \frac{\pi - \Omega_c}{\pi} & n = 0 \\ -\frac{\sin(\Omega_c n)}{n\pi} \text{ for } n \neq 0 & -M \leq n \leq M \end{cases}$$

Bandpass:
$$h(n) = \begin{cases} \frac{\Omega_H - \Omega_L}{\pi} & n = 0 \\ \frac{\sin(\Omega_H n)}{n\pi} - \frac{\sin(\Omega_L n)}{n\pi} \text{ for } n \neq 0 & -M \leq n \leq M \end{cases}$$

Bandstop:
$$h(n) = \begin{cases} \frac{\pi - \Omega_H + \Omega_L}{\pi} & n = 0 \\ -\frac{\sin(\Omega_H n)}{n\pi} + \frac{\sin(\Omega_L n)}{n\pi} \text{ for } n \neq 0 & -M \leq n \leq M \end{cases}$$

Advantages and Disadvantages of Window-Based FIR Design

Advantages:

• Simplicity: Windowing is straightforward and does not require iterative optimization.

• Control over Leakage: Different windows provide different control over sidelobes and main lobe width.

Disadvantages:

• Fixed Frequency Response: Once the window is chosen, the frequency response characteristics are determined.

• Trade-Off Limitations: Some applications require specific frequency responses that cannot be perfectly achieved using standard windows.

Experiment No: 10 Date: 22/10/24

FAMILIARIZATION OF THE ANALOG AND DIGITAL INPUT AND OUTPUT PORTS OF DSP BOARD

Aim:

Familiarization of the analog and digital input and output ports of DSP Boards.

Theory:

TMS 320C674x DSP CPU

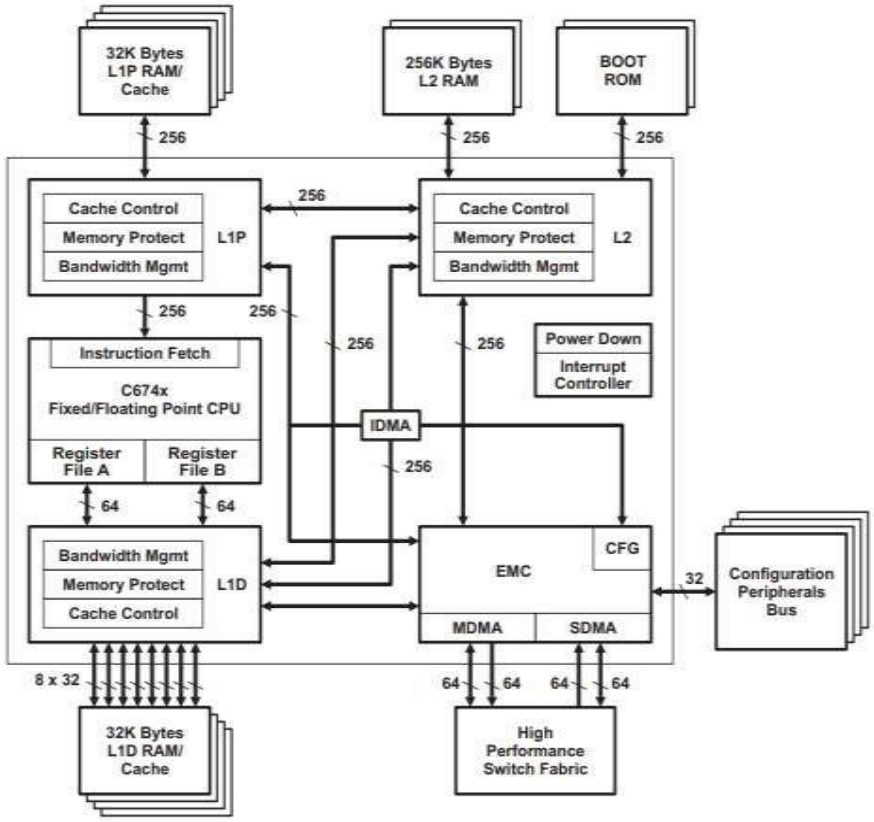

FIGURE: TMS320C 674X DSP CPU BLOCK DIAGRAM

The TMS320C674X DSP CPU consists of eight functional units, two register files, and two data paths as shown in Figure. The two general-purpose register files (A and B) each contain 32 32- bit registers for a total of 64 registers. The general-purpose registers can be used for data or can be data address pointers. The data types supported include packed 8-bit data, packed 16-bit data, 32-bit data, 40- bit data, and 64-bit data. Values larger than 32 bits, such as

40-bit-long or 64-bit-long values are stored in register pairs, with the 32 LSBs of data placed in an even register and the remaining 8 or 32 MSBs in the next upper register (which is always an odd-numbered register). The eight functional units (.M1, .L1, .D1, .S1, .M2, .L2, .D2, and .S2) are each capable of executing one instruction every clock cycle. The .M functional units perform all multiply operations. The .S and .L units perform a general set of arithmetic, logical, and branch functions. The .D units primarily load data from memory to the register file and store results from the register file into memory.

Multichannel Audio Serial Port (McASP):

The McASP serial port is specifically designed for multichannel audio applications.
Its key features are:

• Flexible clock and frame sync generation logic and on-chip dividers

• Up to sixteen transmit or receive data pins and serializers

• Large number of serial data format options, including: – TDM Frames with 2 to 32 time slots per frame (periodic) or 1 slot per frame (burst) – Time slots of 8,12,16, 20, 24, 28, and 32 bits – First bit delay 0, 1, or 2 clocks – MSB or LSB first bit order – Left- or right-aligned datawords within time slots

• DIT Mode with 384-bit Channel Status and 384-bit User Data registers

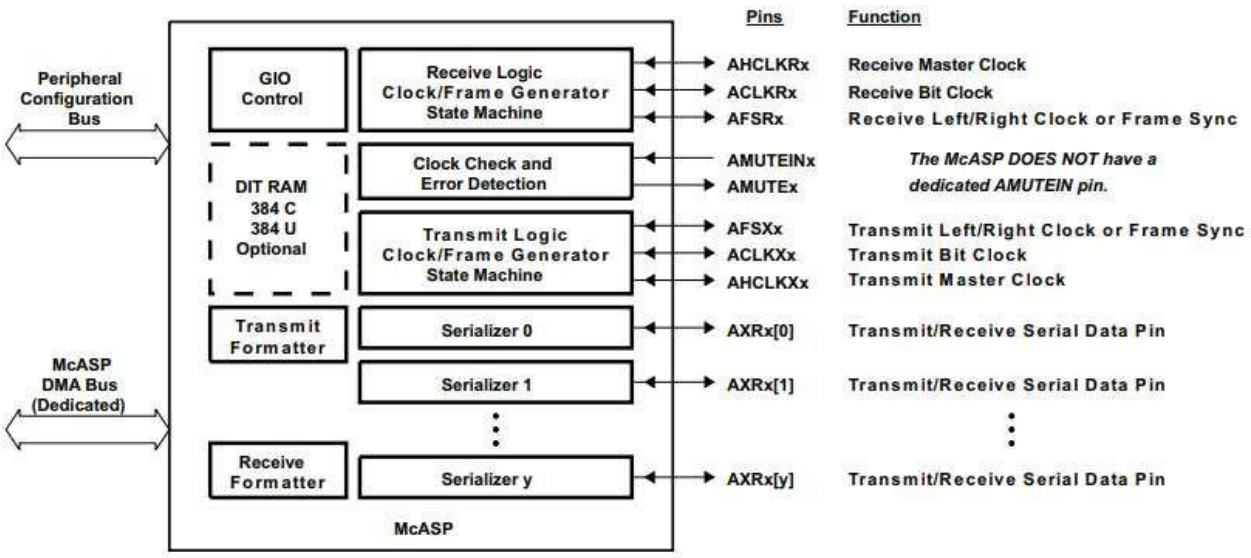
• Extensive error checking and mute generation logic

• All unused pins GPIO-capable

• Transmit & Receive FIFO Buffers allow the McASP to operate at a higher sample rate by making it more tolerant to DMA latency.

• Dynamic Adjustment of Clock Dividers – Clock Divider Value may be changed without resetting the McASP. The DSK board includes the TLV320AIC23 (AIC23) codec for input and output.

The ADC circuitry on the codec converts the input analog signal to a digital representation to be processed by the DSP. The maximum level of the input signal to be converted is determined by the specific ADC circuitry on the codec, which is 6 V p-p with the onboard codec. After the captured signal is processed, the result needs.
to be sent to the outside world. DAC, which performs the reverse operation of the ADC. An output filter smooths out or reconstructs the output signal. ADC, DAC, and all required filtering functions are performed by the single-chip codec AIC23 on board the DSK.



Result:

Familiarized the input and output ports of dsp board.

Experiment No: 11 Date: 29/10/24

Generation of Sine Wave using DSP Kit

Aim:

To generate a sine wave using DSP Kit.

Theory:

Sinusoidal are the smoothest signals with no abrupt variation in their amplitude, the amplitude witnesses gradual change with time. Sinusoidal signals can be defined as a periodic signal with waveform as that of a sine wave. The amplitude of sine wave increases from a value of 0 at 0° angle to a maximum value of 1 at 90°, it further reaches its minimum value of -1 at 270° and then returns to 0 at 360°. After any angle greater than 360°, the sinusoidal signal repeats the values so we can say that period of sinusoidal signal is 2π i.e. 360°.If we observe the graph, we can see that the amplitude varying gradually with a maximum value of 1 and a minimum value of -1. We can also observe that the wave begins to repeat its value after a period or angle value of 2π hence periodicity of sinusoidal signal is 2π.

$$y(t)=A\sin(\omega t+\phi)+C$$

Procedure

1. Open Code Composer Studio, Click on File - New – CCS Project
Select the Target – C674X Floating point DSP , TMS320C6748 , and
Connection – Texas Instruments XDS 100v2 USB Debug Probe and Verify.
Give the project name and select Finish.
2. Type the code program for generating the sine wave and choose
File – Save As and then save the program with a name including ‘main.c’.
Delete the already existing main.c program.
3. Select Debug and once finished, select the Run option.
4. From the Tools Bar, select Graphs – Single Time.
Select the DSP Data Type as 32-bit Floating point and time display unit as second(s).
Change the Start address with the array name used in the program(here,s).
5. Click OK to apply the settings and Run the program or clock Resume in CCS.

Program:

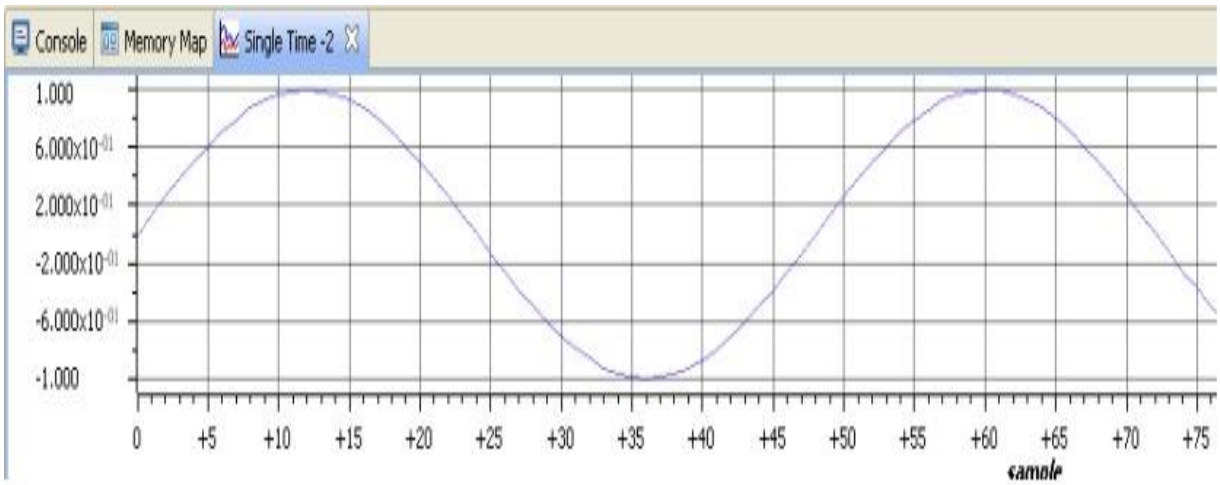
```
#include<stdio.h>
#include<math.h>
#define pi 3.14159
float s[100];
void main()
{
int i;
float f=100, Fs=10000;
for(i=0;i<100;i++)
```

```
s[i]=sin(2*pi*f*i/Fs);
}
```

Result:

Generated sine wave using DSP Kit.

Observation:



Experiment No:12 Date:29/10/24

Linear Convolution using DSP Kit

Aim:

To perform linear convolution of two sequences using DSP Kit.

Theory:

Linear convolution is one of the fundamental operations used extensively in signal and system in electrical engineering. It has applications in areas like audio processing, signal filtering, imaging, communication systems and more. In simple terms, linear convolution is the process of combining two signals or functions to produce a third signal or function.
Formally, the linear convolution of two functions f(t) and g(t) is defined as:
The formula for linear convolution of two discrete signals x[n] and h[n] is given by:

$$y[n] = \sum_{k=-\infty}^{\infty} x[k].h[n-k]$$

In the context of linear convolution in DSP, this operation is applied to digital signals. DSP systems utilize algorithms to perform convolution efficiently, often leveraging Fast Convolution methods to handle large datasets and real-time processing.

Procedure

1. Set Up New CCS Project
Open Code Composer Studio.
Go to File → New → CCS Project.
Target Selection: Choose C674X Floating point DSP, TMS320C6748.
Connection: Select Texas Instruments XDS 100v2 USB Debug Probe.
Name the project and click Finish.

2. Write and Configure the Program
Write the C code for generating and storing a sine wave, configuring it to access data at specified memory locations.
Assign the input Xn and filter Hn values to specified addresses:
Xn: Start at 0x80010000, populate subsequent values at offsets like 0x80010004 for each additional input.
Hn: Start at 0x80011000 with similar offsets for additional values.
Lengths of Xn and Hn should be defined at 0x80012000 and 0x80012004, respectively.

3. Configure Output Location in Code
In the code, configure the output to store convolution results at specific memory addresses starting from 0x80013000, with each result at an offset of 0x04.

4. Save the Program
Go to File → Save As and save the code with a filename like main.c.
Remove any default main.c program that might exist in the project.

5. Build and Debug the Program
Select Debug to build and load the program on the DSP.
Once the build is complete, select Run to execute.

6. Execute and Verify Output
In the Debug perspective, click Resume to run the code.
Use the Memory Browser in Code Composer Studio to verify the output at the memory location 0x80013000:
Check 0x80013000 for the first convolution result, 0x80013004 for the second, and so on.
Cross-check the values with the expected convolution results for accuracy.

Program:

```
#include<fastmath67x.h>
#include<math.h>
void main()
{
int *Xn,*Hn,*Output;
int *XnLength,*HnLength;
int i,k,n,l,m;
Xn=(int *)0x80010000; //input x(n)
Hn=(int *)0x80011000; //input h(n)
XnLength=(int *)0x80012000; //x(n) length
HnLength=(int *)0x80012004; //h(n) length
Output=(int *)0x80013000; // output address
l=*XnLength; // copy x(n) from memory address to variable l
m=*HnLength; // copy h(n) from memory address to variable m
for(i=0;i<(l+m-1);i++) // memory clear
{
Output[i]=0; // o/p array
Xn[l+i]=0; // i/p array
Hn[m+i]=0; // i/p array
}
for(n=0;n<(l+m-1);n++)
{
for(k=0;k<=n;k++)
{
Output[n] =Output[n] + (Xn[k]*Hn[n-k]); // convolution operation.
}
}
}
```

Result:

Performed Linear Convolution using DSP Kit.

.

Observation:

Xn
0x80010000 – 1
0x80010004 – 2
0x80010008 – 3

Hn
0x80011000 – 1
0x80011004 – 2

XnLength
0x80012000 – 3

HnLength
0x80012004 – 2

Output
0x80013000 – 1
0x80013004 – 4
0x80013008 – 7
0x8001300C – 6
